- ▶ In Component Based Software Engineering a component is defined as a unit of composition with contractually specified interfaces that performs a required task.
- ▶ Identifying and selecting a component according to given requirements from a vast set of components available is a tedious task

- ▶ Before starting to build anything, it is always better to know why we need it.
- ▶ Reducing the search space in component selection helps in faster development.
- ▶ **So a method is required that reduces the search space and gives out components that are according to the requirements specified**

- ▶ Agglomerative Hierarchical Clustering is performed on all the components to generate a hierarchy of components available
- ▶ User feeds the Application Requirements using a web browser tool
- ▶ The component is identified by following the hierarchy according to the given requirements

- ▶ Each software Component has various features that includes name, language , type of component, domain, visibility and functionality
- ▶ functionality will be used for fine grained searching
- ▶ name and id is for distinguishing each component
- ▶ rest all will be used for measuring similarity for clustering the components.

- ▶ Agglomerative hierarchical clustering is a unsupervised learning algorithm
- ▶ It groups similar feature vectors into groups
- ▶ initially each feature vector is considered a individual cluster
- ▶ until the number of clusters does not reduce to one:-
 1. compute similarity of each feature vector
 2. merge the 2 most similar feature vectors
 3. update the similarity matrix
- ▶ a hierarchy of feature vectors is generated

Algorithm 1: Component Clustering

Result: one or more clusters

Input: The set $X = \{x_1, x_2, \dots, x_n\}$ and the similarities $s(x_i, x_j), 1 \leq i, j \leq n$

Limit=1 ,N=n

for $1 \leq i, j \leq N, i \neq j$ **do**

$\text{sim}(G_i, G_j) = s(x_i, x_j)$

end

while $N \neq \text{Limit}$ **do**

$N=N-1$

 Find pair of clusters G_p and G_q such that

$\text{sim}(G_p, G_q) = \max\{x \in G_i, y \in G_j \mid s(x, y)\}$

 update $\text{sim}(G_i, G_j)$

end

Figure 1: Hierarchical Clustering of Components

- ▶ after getting a subset of components using the clusters generated and requirements Fine grained searching is performed to get the exact set of components along with the similarity scores
- ▶ algorithm to get the similarity score of requirements keywords and functionality attribute of each component in the subset of components
- ▶ the similarity score is based on the $\text{number of keywords matched} / \text{number of words}$ in functionality

Algorithm 2: Fine grained Searching

Result: Similarity Score for every component in x with requirement

Input: The set $X = \{x_1, x_2, \dots, x_n\}$

$i=1$

while $i \neq n$ **do**

$i=i+1$

$matched=0$

for $keyword \leftarrow keywords$ **do**

if $keyword \in x_i$ **then**

$matched \leftarrow matched + 1$

end

end

$similarityScore \leftarrow matched \div len(x_i)$

end

1. AHC algorithm is performed on all the components
2. currently requirements are fed directly in code
3. keywords are generated from the requirements by removing punctuation and stop words
4. the cluster names are matched with keywords ,on matching the set of components for fine grained searching is reduced
5. fine grained search is performed on the subset of components and all the components are displayed in that cluster along with similarity score

The query text given is "A java component for railway reservation containing login using username and password with captcha functionality , date picker , dropdown for cities , train class and quota , calculation of fare with distance , train class and quota , dedicated payment page with options like debit card , credit card , upi , page to display list of trains "

Figure 3: Comparison with an expert

	Component Name	Language	Functionality	similarityScore
10	Fare Calculator	Java	fare calculation according to distance , train...	0.309859
25	Train Selector	Java	dropdown displaying train class and quota	0.243902
0	Login	Java	Login using username and password	0.212121
1	Login	Java	Login using username and password with captcha...	0.192982
17	Train Display	Java	display list of trains according to origin and...	0.142857
29	Calculate Button	Java	Calculate Button	0.125000
13	Payment	Java	payment page displaying options like credit ca...	0.095238
8	Tax Calculator	Java	tax calculation	0.066667
2	Date Picker	Java	calendar to pick dates	0.045455
15	Payment Handler	Java	handle payment from user	0.040000

References

- ▶ The login component with captcha is found to have less similarity than simple username and password component
- ▶ City selector component was not picked up in the subset of components for fine grained search

- ▶ Searching for reusable components according to given requirements gets challenging with the increase in number of components developed
- ▶ Reducing search space using component attributes while searching for components will be helpful in faster and correct retrieval.
- ▶ AHC is helpful in grouping together of components according to similarity based on domain , programming language ,visibility and type.
- ▶ The hierarchy generated reduces the need to perform fine grained searching on all the components.

- ▶ Representation of Components using formal methods
- ▶ Better fine grained searching using natural language processing techniques
- ▶ using weights to some key requirements like language and domain
- ▶ getting ratings about the search results for performing supervised learning algorithms
- ▶ Compose an application using the search performed
